Practical Activity 7 Classification using neural network

December 27, 2020

1 Practical Activity 7

1.1 Classification Using Neural Networks

This notebook is an exercise for developing a Neural Network (NN) classifier for predicting presence of diabetes in patients. We apply the concepts discussed in Week 7. We walk through NN Classifier in this practical.

Note: this activity is unmarked. It develops your skills for predictive model development using NN.

1.2 Task

Our aim is to build a classification model to predict diabetes. We will be using the diabetes dataset which contains 768 observations and 9 variables, as below: - Pregnancies - Number of times pregnant. - Glucose - Plasma glucose concentration. - BloodPressure - Diastolic blood pressure (mm Hg). - SkinThickness - Skinfold thickness (mm). - Insulin - Hour serum insulin (mu U/ml). - BMI - Basal metabolic rate (weight in kg/height in m). - DiabetesPedigreeFunction - Diabetes pedigree function. - Age - Age in years. - Outcome - "1" represents the presence of diabetes while "0" represents the absence of it.

The dataset is available at https://www.kaggle.com/uciml/pima-indians-diabetes-database

1.3 Evaluation Metric

We will evaluate the performance of the model using accuracy, which represents the percentage of correctly classified samples.

1.3.1 Step 1 - Loading the required libraries and modules.

```
[1]: # Import required libraries
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import sklearn
from sklearn.neural_network import MLPClassifier
from sklearn.model_selection import train_test_split
```

1.3.2 Step 2 - Reading the data and performing basic data checks.

```
[2]: #read in the data as pandas dataframe
     df = pd.read_csv('diabetes.csv')
     #prints the shape - 768 observations of 9 variables.
     print(df.shape)
     #summary statistics of the variables.
     df.describe()
    (768, 9)

                                                1
     3
                            0.167
                                     21
                                                0
                            2.288
                                     33
                                                1
```

The above summary for the 'Outcome' variable, we observe that the mean value is 0.35, which means that around 35 percent of the observations in the dataset have diabetes.

1.3.3 Step 3 - Creating the training and test datasets.

```
[4]: from sklearn.model_selection import train_test_split
     train, test = train_test_split(df, test_size = 0.3, stratify = df['Outcome'])
     X_train = train.drop('Outcome', axis=1)
     y_train = train['Outcome']
     X test = test.drop('Outcome', axis = 1)
     y_test = test['Outcome']
     print(X_train.shape)
     print(X_test.shape)
```

(537, 8)(231, 8)

1.3.4 Step 4 - Building the neural network model.

Inthis will build step, we the neural network model using the Classifier' https://scikitsklearn's 'Multi-Laver Perceptron library learn.org/stable/modules/generated/sklearn.neural_network.MLPClassifier.html. We will use three hidden layers with the same number of neurons as the number of features in the dataset.

We will also select 'relu' as the activation function and 'adam' as the solver for weight optimization. To learn more about 'relu' and 'adam', please refer to the Deep Learning with Keras guides here.

```
[5]: from sklearn.neural_network import MLPClassifier
     mlp = MLPClassifier(hidden_layer_sizes = (8, 8, 8),
                         activation = 'relu',
                         solver = 'adam',
                         max_iter = 500
    mlp.fit(X_train,y_train)
```

```

    packages\sklearn\neural_network\_multilayer_perceptron.py:585:
    ConvergenceWarning: Stochastic Optimizer: Maximum iterations (500) reached and
    the optimization hasn't converged yet.
      % self.max iter, ConvergenceWarning)
[5]: MLPClassifier(hidden_layer_sizes=(8, 8, 8), max_iter=500)
```

1.3.5 Step 5 - Evaluating the neural network model.

```
[6]: predict_train = mlp.predict(X_train)
    predict_test = mlp.predict(X_test)

from sklearn.metrics import accuracy_score
    print(accuracy_score(y_train, predict_train))
```

0.7094972067039106

The above output shows the performance of the model on training data. The accuracy is around 0.70.

Next step is to evaluate the performance of the model on the test data that is done with the lines of code below.

```
[7]: print(accuracy_score(y_test, predict_test))
```

0.7142857142857143

2 Task

Try to find the best set of parameters for the NN model.
